Solution (1) Since each column contains n elements, this operation takes $(n \log p)$ time on a hypercube-connected parallel computer. Therefore, the parallel run time is $TP = n^3/p + (n^2 \log p)$. The isoefficiency function due to communication is $(p \log p)^3$, which is the overall isoefficiency function.

The total problem size is proportional to the number of processors used. Goal is to run larger problem in same amount of time. Perfect scaling means problem P_x runs in same time as single processor run. The ability of a parallel program's performance to scale is a result of a number of interrelated factors.
